

## **PHASE 6: PROJECT TESTING**

### **6.1 Objective**

The objective of the Testing Phase is to verify that the automated flow behaves correctly under different request conditions.

Testing ensures that the automation follows the intended path and that the configured actions occur correctly.

### **6.2 Valid Standard Laptop Request Test**

A valid standard laptop request is submitted through the Service Catalog.

The purpose of this test is to verify that the request is accepted and processed by the automation.

### **6.3 Trigger Verification**

The next test verifies whether the configured trigger starts the flow when the relevant request is submitted.

The expected result is that the automation begins correctly.

### **6.4 Condition Verification**

The standard laptop condition is tested to ensure that the system correctly identifies the intended request type.

The purpose is to verify that the condition controls whether the automation should continue.

### **6.5 Approval Testing**

The approval process is tested using an approved response.

The expected behaviour is that the request moves into the approved path and continues with the configured fulfilment or subsequent actions.

### **6.6 Rejection Testing**

The rejection path is tested using a rejected response.

The expected behaviour is that the request follows the rejection branch rather than continuing through the approved path.

### **6.7 Notification Testing**

Notifications are verified to ensure that the appropriate communication or request updates occur as configured.

### **6.8 Status Testing**

Request status changes are checked to confirm that the workflow provides the expected process visibility.

### **6.9 Fulfilment Testing**

Fulfilment actions are verified to ensure that approved requests continue through the intended processing steps.

### **6.10 Non-Standard Request Testing**

Non-standard requests are also tested.

The objective is to verify that they do not incorrectly follow the standard laptop automation.

### **6.11 Issue Identification and Correction**

During testing, any issues identified in the workflow configuration are recorded and corrected before the final demonstration.

### **6.12 Expected Output**

The flow should complete the intended automation path without errors for valid test cases.

Rejected and non-applicable cases should follow their respective paths.

### **6.13 Phase Result**

Testing provides evidence that the flow performs the intended trigger, condition evaluation, approval, rejection, notification, status, and fulfilment activities.
