

PHASE 2: REQUIREMENT ANALYSIS

2.1 Objective

The objective of the Requirement Analysis Phase is to identify the functional requirements of the laptop procurement process before designing the automation.

This phase focuses on understanding:

- Who submits the request.
- Who approves the request.
- What information is required.
- Which requests are considered standard laptop requests.
- What should happen after approval.
- What should happen after rejection.
- How the status of the request should be communicated.

2.2 Identification of Users

The project identifies the main user roles involved in the process.

Requester

The requester is the employee or user who submits the standard laptop request through the Service Catalog.

Approver

The approver is the person or group responsible for reviewing the request and deciding whether it should proceed.

IT Team

The IT team is responsible for the fulfilment-related work generated by the automated process.

2.3 Request Information

The system requires appropriate information from the requester. This includes the laptop requirement and relevant request details.

The information submitted by the requester becomes part of the data used by the automation.

2.4 Identification of Standard Laptop Requests

A condition is required to identify whether the submitted request corresponds to a **standard laptop order**.

This condition ensures that the configured automation is applied to the intended requests and prevents non-standard requests from incorrectly following the same workflow.

2.5 Approval Requirement

An approval stage is included before procurement or fulfilment continues.

The workflow therefore separates the initial request from the later fulfilment activities.

2.6 Approved Request

When the request is approved, the flow continues into the fulfilment or subsequent automation process.

The approval outcome acts as a decision point in the workflow.

2.7 Rejected Request

When the request is rejected, the automation follows a separate rejection path.

This path is designed to update the request appropriately and inform the requester.

2.8 Status and Visibility Requirements

The project also identifies the need for status updates and process visibility. This allows the users involved in the request to understand the stage of processing.

2.9 Requirement Workflow

The complete requirement-level process can be represented as:

Request Submission → Validation/Condition → Approval → Fulfilment/Notification → Completion

2.10 Expected Output

The output of this phase is a clearly defined set of functional requirements and a logical request-processing workflow.

The requirement analysis establishes the inputs, approval mechanism, conditions, subsequent actions, rejection handling, and status visibility needed for the project.

2.11 Phase Result

At the end of Phase 2, the team had a clear understanding of what the system should accept, how the request should be evaluated, how approval should be handled, and what actions should occur for approved and rejected requests.
