

PHASE 3: PROJECT DESIGN

3.1 Objective

The objective of the Project Design Phase is to convert the requirements into a logical workflow structure before implementing the solution in Flow Designer.

This phase focuses on designing the sequence of automation activities.

3.2 Trigger Design

The first component of the workflow is the trigger.

The trigger is designed to start the automation when the required procurement request is created or submitted.

The trigger represents the starting point of the automated process.

3.3 Condition Design

After the trigger, a condition is included to determine whether the request is a standard laptop order.

The condition is important because the automation is specifically designed for standard laptop requests.

3.4 Approval Design

The next component is the approval stage.

The flow is designed to send the request through the required approval process using the appropriate approver.

This creates a controlled decision point before fulfilment.

3.5 Approved Branch

The approved branch represents the successful path of the workflow.

After approval, the request continues into the fulfilment process and any required subsequent actions.

3.6 Rejected Branch

The rejected branch provides an alternative path for requests that are not approved.

This branch is intended to update the request appropriately and communicate the outcome to the requester.

3.7 Notification Design

Notifications and status updates are included in the design so that users can track the request throughout the process.

The design therefore considers both automation and process visibility.

3.8 Data Mapping

Data must move correctly from the initial request into the subsequent Flow Designer actions.

The project therefore includes mapping the relevant data between the trigger and the following actions.

3.9 High-Level Workflow

The final high-level design is:

**Trigger → Condition → Approval → Approved/Rejected Branch →
Fulfilment/Notification → Completion**

This workflow forms the logical foundation of the final ServiceNow implementation.

3.10 Expected Output

The expected output of Phase 3 is a complete high-level workflow design that can be implemented using Flow Designer.

3.11 Phase Result

At the end of this phase, the automation sequence, decision points, branches, notifications, and data flow were logically defined.
